If we calculate the predicted runtime over a large range using all values $\hat{\epsilon}$ of n from 1070 to $n < 10350$, we can, to within a constant, predict attack cost for $\hat{\epsilon}$. If we calculate the predicted running time over a large range using all values $\hat{\epsilon}$ of n from 1070 to $n < 10350$, we can predict the cost of an attack for n to within a constant. Example 3. Let us have a system with n inputs and an output, each of which is connected to one of the inputs. This system has n inputs and one output. The probability that in time t the system will reach the state that should be reached in time t is $m < 1$. If you calculate it for a system consisting of n
